ABSTRACT

Aim of study to investigate the effect of certain natural products from medicinal plants as adjuvant systems to reduce toxicity of chemotherapy. cyclophosphamide (CTX) is an anti-cancer DNA alkylating chemotherapeutic agent to act against a variety of tumors in head and neck, testicular, ovarian, bladder, small-cell lung cancers, this study performed to investigate the effect of Berberis vulgaris in combination with CTX on hematological and physiological parameters induced by CTX in mice. In this study we evaluate the possible protective effects of Berberis vulgaris on hematological and physiological parameters in mice chronically treated with CTX. Four groups of mice were examined: a control (I), mice treated with CTX (II), mice treated with CTX + Berberis vulgaris (III), and mice treated with Berberis vulgaris (IV). All animals were treated for successively 5 days and killed one week after the last treatment. The results show significant decreases in levels of red blood cell distribution width (RDW), white blood cells (WBCs), neutrophils and lymphocytes counts with increases in levels of monocytes. Also, hepatocytes oxidative stress which characterized by significant increases in the serum activities aspartate aminotransferase (AST), alanine aminotransferase (ALT). Berberis vulgaris combined with CTX or Berberis vulgaris alone successfully normalized the hematological and biochemical parameters in form returning (RDW), (WBCs), monocytes and lymphocytes counts to normal level. Hepatocytes oxidative stress which characterized by significant decrease in the serum activities of (AST) and (ALT).

INTRODUCTION: Herbal medicines derived from plant extracts are being increasingly utilized to treat a wide variety of clinical disease (Gupta et al., 2004). Because of the concerns about the side effects of conventional medicine, the use of natural products as an alternative or supportive for conventional treatment in healing and treatment of various diseases has been on the rise in the last few decades (Salem, 2005). A larger number of these plants and their isolated constituents have shown beneficial therapeutic effects, anti-inflammatory, anti-cancer and anti-microbial effects (Miller et al., 2004). The B. vulgaris act as anticancer agent. Berberine inhibits cyclooxygenase-2 transcriptional activity in human colon cancer cells (Fukuda et al., 1999) and (Lin et al., 1999) and preliminary studies have shown that berberine sulfate inhibits tumor promoting activity of teleocidin (Nishino et al., 1986). Berberine also inhibits DNA topoisomerase I and II in biochemical system (Wang et al., 1996) and (Kim et al., 1998). The antioxidant activity of berberine has been widely demonstrated. It was reported that berberine can scavenge ROS and reactive nitrogen species (RNS) (Jung et al., 2009). Asai and co-workers reported that berberine can reduce Aβ levels by altering APP processing in human neuroglioma H4 cells that stably express Swedish-type of APP at the range of berberine concentration (0.1-100µM) without cellular toxicity (Asai et al., 2007). Although CTX is a drug widely applied in the treatment of malignant and nonmalignant tumors, the clinical outcomes of treatments with these agents are severely limited, mostly due to its toxicity to normal tissues. The predominant toxicity of CTX is bone marrow suppression. The resultant granulocytopenia greatly increases the risk of serious infection in patients undergoing cancer treatment (Ladisch et al., 1978). Therefore, it is necessary to develop adjuvant therapy which may be used in combination with CTX to improve the efficacy of the treatment or reduce the associated undesirable side effects (Robak et al., 2010).

MATERIALS AND METHODS

Experimental Animals: Adult female Swiss albino mice weighting 23±2 g was used in this study. Animals were housed (5 animals per cage) at the animal house at Zoology Department, Faculty of Science (Omar AL-Mukhtar University, Albida) in clean and dry plastic cages, in 12h/12h dark/light cycle under laboratory condition of temperature and humidity. Mice were divided into four groups, a control mouse with saline PBS solution (group I), mice injected with a single dose of CTX at a dose of 200 mg/Kg “4 mg/mouse” (group II), mice treated with CTX at a dose of 200 mg/Kg and administered with vulgaris at a dose of vulgaris “200 µg/mouse orally” (group III), and normal mice administered with a single dose of vulgaris alone “200 µg/mouse orally” (group IV).

Evaluation of hematological parameters: Blood samples with anti-coagulant EDTA were analyzed for hematological parameters of red blood cells distribution width (RDW) counts, White Blood Cell (WBC) counts and total number of lymphocytes according to Feldman (Mohamed, 2021).

Serum biochemical analysis: Serum activities of aspartate aminotransferase (AST), and alanine aminotransferase (ALT) were determined colorimetrically using kits obtained from Diamond Diagnostic, Egypt according to the methods of Bruins and Ash wood or Kind and King (Kind and King, 1954).

Statistical analysis: Data was statistically analyzed by ANOVA with post-hock Dennett’s multiple comparisons test using statistical software program (Graph Pad Prism version 7.30). Differences were considered significant at p<0.05.
RESULTS: Figure 1 and 2 showed that CTX treatment significantly decreased the total numbers of white blood cells coincided with decreases in the number of lymphocytes when compared to normal group. The co-treatment with vulgaris returned the white blood cells to its normal coinciding with recovery of the relative numbers of lymphocytes as compared to control values (PBS group).

Table 1: showed that CTX treatment significantly decreased the total numbers of neutrophils and RDW coincided with increases in the number of monocyte when compared to normal group. The co-treatment with vulgaris returned the RDW to its normal coinciding with recovery of the relative numbers of monocyte and higher numbers of neutrophils as compared to control values (PBS group).

DISCUSSION: The study was conducted to evaluate the effect of the administration of Vulgaris on hematological, biochemical parameters alteration and to reduce the toxicity induced by a high dose of the anticancer drug CTX in mice. First of all, we found that mice who received treatment with CTX induced a marked decrease in the total number of leukocytes mainly in neutrophils count, however, this treatment was also associated with induced decreases in the number of lymphocytes and increases of monocytes. These data are consistent with data reported by Huyan et al. (2011) on the effect of CTX in mice. Also in our study, the results indicated that numbers of leukocytes, lymphocytes, and neutrophils during vulgaris injection alone or in combination with CTX treatment. Consistent with these results Liu et al. (1996). Interestingly, the total number of leukocytes increased after treatment with CTX and vulgaris as well as the number of lymphocytes, and neutrophils with decreases the number of monocytes. These results are in line with the previous investigations which demonstrate that vulgaris has a cytoprotective effect on lymphocytes to enhance the immune responses and to stimulate the production of lymphocytes (Majdalawieh et al., 2010). By evaluating the biochemical changes, we found the CTX treatment associates with a dysregulation in liver functions and oxidative stress. CTX is catabolized by ALDH which is an NADP-dependent enzyme, it is well known that hepatocytes and hematopoetic stem cells produce a high amount of ALDH make them relatively resistant to CTX while it is cytoprotective to mature hematopoetic progenitors and lymphocytes (Emadi et al., 2009). Furthermore,
several studies confirmed CTX leads to oxidative stress as strong depletion of antioxidants enzyme activities (Premkumar et al., 2001). CTX induces liver function alterations by modulating all liver enzymes (Davila et al., 1989). The liver is the richest source of both GOT and GPT enzymes, so any damage to the liver cells will increase in both of these enzymes (Cole and Bradley, 1973). Increased tissue ALP is the main stigma of chemical-induced tissue injury along with hepatocellular necrosis. The elevation of AST and ALP recorded in the present findings are consistent with (Senthilkumar et al., 2006). ALP is now frequently detected to estimate the degree of liver dysfunction due to CTX of advanced liver cirrhosis as well as the expectation of heart failure development (Mohamed, 2021).
